

ABSTRACT

5 The method consists of computing (E1-E4) a set of two-
dimensional images in a three-dimensional geometrical space
representing a virtual object from respective different viewpoints. The
virtual object is represented by digital data stored in a computer.
Holograms are computed (E5-E6) for the respective two-dimensional
10 images using a fast complex transform, such as a Fourier transform. The
holograms are then juxtaposed (E7) to form a digital hologram of the
object which is physically reproduced (E8) by a spatial light modulator. A
three-dimensional image of the object is obtained by illuminating the
spatial light modulator with a coherent source.
